

How does microgridgenerator work?

MicrogridGenerator contains functionality to generate a list of microgrids. For each requested microgrid, the process proceeds as follows. First, the maximum power of the load is generated randomly. A load file is then randomly selected and scaled to the previously generated value.

How do I run a microgrid?

Running the microgrid is straightforward. Simply pass an action for each fixed module to `microgrid.run`. The microgrid can also provide you a random action by calling `microgrid.sample_action`. Once the microgrid has been run for a certain number of steps, results can be viewed by calling `microgrid.get_log`.

What is a microgrid & how does it work?

Microgrids are defined as "a cluster of loads, distributed generation units and energy storage systems operated in coordination to reliably supply electricity, connected to the host power system at the distribution level at a single point of connection, "the point of common coupling" (PCC) (Figure 1) .

How does pymgrid work?

pymgrid consists of three main components: a data folder containing load and PV production time series that are used to 'seed' microgrids, a microgrid generator class named `MicrogridGenerator`, and a microgrid simulator class called `Microgrid`. In order to easily generate microgrids, pymgrid ships with load and PV production datasets.
